

Categorising and aligning entries in Index

[Stack Exchange Post](#) | 20 April 2021 (Tuesday)

For the alignment of the page numbers you can write an index style file (`.ist`). The important keys here are `delim0`, `delim1` and `delim2`. You can set them for `\hfill` to flush right, with the backslash escaped (so `\\hfill`).

For the alignment of the items you can redefine `\subitem` to `\@idxitem`, basically pretending that each individual kanji is a category, for layout purposes.

In the MWE below the `.ist` file is contained within the LaTeX source using `filecontents`, this is just for the example. You can either run it once or copy the contents manually to a file, then remove this part from the code. Note that the file name for the `filecontents` environment is set to be `\jobname.ist`, where the macro `\jobname` defaults to the name of the `.tex` file without the extension. If you use a file with a different name then you should also change the option setting `options=-s \jobname.ist` in `\makeindex` to the actual file, for example `options=-s mysettings.ist`.

```
\documentclass[10pt, a4paper]{ltjbook}
\usepackage{luatexja}
\usepackage{imakeidx}
\begin{filecontents*}{\jobname.ist}
delim_0 "\\hfill"
delim_1 "\\hfill"
delim_2 "\\hfill"
\end{filecontents*}
\makeindex[name=stroke, columns=4, title={Index of 漢字 by Stroke Count},
intoc, columnseprule,options=-s \jobname.ist]
\newcommand{\strindex}[2]{\index[stroke]{#1@\textbf{#1 strokes}!#2}}
\makeatletter
\let\subitem\@idxitem
\makeatother
```

Edit for kanji with one stroke: you can print the `s` conditionally using `\ifnum`.

```
\newcommand{\strindex}[2]{\index[stroke]{#1@\textbf{#1 stroke\ifnum#1>1s\fi}!#2}}
```
